## Abstract

Recently, John Butcher developed a MAPLE code 'Test 21' to solve the order conditions directly. This code was applied to derive 13-stage pairs of orders 7 and 8 and unexpectedly, revealed the existence of some previously unknown pairs. This talk reports formulas for directly deriving such a new parametric family.

# Explicit Runge–Kutta pairs of methods

For a vector initial value problem in ordinary differential equations:

$$y' = f(x, y), \quad y(x_0) = y_0,$$

an  $s$ -stage explicit Runge–Kutta **pair** is defined for a step of  $h$  as,

$$Y^{[i]} = y_{n-1} + h * \sum_{j=1}^{i-1} a_{i,j} f(x_{n-1} + c_j h, Y^{[j]}), \quad i = 1, \dots, s,$$

$$y_n = y_{n-1} + h * \sum_{i=1}^s b_i f(x_{n-1} + h, Y^{[i]}), \quad n = 1, \dots,$$

$$\widehat{y}_n = y_{n-1} + h * \sum_{i=1}^s \widehat{b}_i f(x_{n-1} + h, Y^{[i]}), \quad n = 1, \dots,$$

- where  $\{b_i, \widehat{b}_i, a_{i,j}, c_i\}$  are coefficients of the pair,
- $y_n$  approximates  $y(x_n)$  to order  $p$ ,
- the difference  $y_n - \widehat{y}_n$  is an order  $p - 1$  estimate of the local truncation error that can be used for stepsize control.

- This is a study to formulate some specific new pairs.
- Better methods would lead to improvements in software for IVPs - hence, there has since been a search for better methods.
- In 2021, John Butcher developed the MAPLE program 'Test21' which solves order conditions directly to obtain some (explicit) Runge–Kutta methods.
- **Some new R–K *pairs* were found on applying 'Test21'.**
  - These new pairs were members of a parametric family.
  - Knowledge of the structure of these new methods may yield more methods in this family.
  - The structure for these new methods may lead to **other types of new methods**.
  - Does this new family contain methods better than those already known?

# Order Conditions are generated by Rooted Trees

Two similar standard order conditions are

$$\sum_{i,j} b_i a_{i,j} c_j^2 = 1/(1 * 1 * 3 * 4)$$

$$\sum_i b_i c_i^3 / 3 = 1/(1 * 1 * 1 * 4) / 3$$

# Order Conditions are generated by Rooted Trees

Two similar standard order conditions are

$$\sum_{i,j} b_i a_{i,j} c_j^2 = 1/(1 * 1 * 3 * 4)$$

$$\sum_i b_i c_i^3 / 3 = 1/(1 * 1 * 1 * 4) / 3$$

The difference gives a 'Singly Orthogonal Order Condition':

$$\sum_{i,j} b_i (a_{i,j} c_j^2 - \frac{c_i^3}{3}) = 0$$

We define "stage-order" or "subquadrature" expressions as

$$q^{[k]} = (AC^{k-1} - C^k/k),$$

to find that vector  $\mathbf{b}$  must be orthogonal to vector  $\mathbf{q}^{[3]}$ .

$$\sum_i b_i c_i^3 / 3 = 1/(1 * 1 * 1 * 4) / 3$$

The difference gives a 'Singly Orthogonal Order Condition':

$$\sum_{i,j} b_i (a_{i,j} c_j^2 - \frac{c_i^3}{3}) = 0$$

i.e.  $\mathbf{b.q}^{[3]} = 0$ , and past derivations have relied on making parts of either such order conditions components equal to zero, **but more flexibility is possible.**

# There are only four types of Order Conditions

Order conditions can be partitioned into four types that exist:

- A. Quadrature**   $\sum_i b_i c_i^4 = 1/5 = \int_0^1 c^4 dc$   
k-1 terminal nodes each connected to the root
- B. Linear C.C. N.H.**   $\sum_{i,j,k} b_i a_{i,j} a_{j,k} c_k^3 = 1/120$   
all terminal nodes connected to the penultimate node
- C. Linear V.C.**   $\sum_{i,j,k} b_i c_i^2 a_{i,j} c_j a_{j,k} c_k^2 = 1/120$   
'side' subtrees of single nodes only
- D. Non-Linear**   $\sum_{i,j,k} b_i (a_{i,j} c_j) (a_{i,k} c_k^2) = 1/36$   
at least two subtrees of height two or more

# Vector-Matrix format of Standard Order Conditions

A Vector-Matrix notation is more convenient:

A. Quadrature  $Q^{[5]}=0$

$$bC^4e = 1/5$$

B. Linear Constant Coefficient

$$bA^2C^3e = 1/120$$

C. Linear Variable Coefficient

$$bC^2ACAC^2e = 1/120$$

D. Non-Linear

$$b(ACe).(AC^2e) = 1/36$$

With retained simplifying conditions, Type D conditions collapse to type C. Hence, I will be focusing of how to solve the first three types.

# Otherwise, the order conditions can be expressed using integrals:

If you work with order conditions, the following interpretation as recursive integration may be helpful - for example:

$$bCAC^3AC^2e = \int_{c=0}^1 c \int_{\bar{c}=0}^c \bar{c}^3 \int_{\hat{c}=0}^{\bar{c}} \hat{c}^2 d\hat{c}d\bar{c}dc.$$

- i.e.  $b$  is replaced by integration on  $[0,1]$ ,
- each  $A$  is replaced by integration on  $[0, c]$ ,
- each  $C^k$  is replaced by the form  $\bar{c}^k$ .

Some multiples of these forms can be expressed using specific nodes as convenient.

Such expressions are utilized in proving some order conditions.

Combining *each* Standard Order Condition with an earlier one yields a "Singly Orthogonal Order Condition" (SOOC) from which constants have been eliminated:

A. Quadrature  $5 \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \bullet \\ \bullet \end{array} - 4 \begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \bullet \end{array} \quad b(5C^4 - 4C^3)e = 0$

B. Linear Constant Coefficient  $\begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \bullet \end{array} \quad bAq^{[4]} = 0$

C. Linear Variable Coefficient  $\begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \bullet \\ \bullet \end{array} \quad bC^2ACq^{[3]} = 0$

D. Non Linear  $\begin{array}{c} \bullet \\ \bullet \\ \bullet \\ \bullet \\ \bullet \end{array} \quad b(ACe.q^{[3]}) = 0$

The "subquadratures"  $q^{[k]} = (AC^{k-1} - C^k/k)e$ , show that SOOCs constrain coefficient expressions by orthogonality.

# How many SOOC.s of each type are there?

Type	A	B	C	D	$N_p$	
Order $p$						
(1)	(1)				(1)	$(\sum b_i = 1)$
2	1				1	$\sum b_i(1 - 2c_i) = 0$
3	1	1			2	.
4	1	2	1		4	.
5	1	3	4	1	9	.
6	1	4	11	4	20	.
7	1	5	26	16	48	.
8	1	6	57	51	115	.
<u>Totals</u>	<u>8</u>	<u>21</u>	<u>99</u>	<u>72</u>	<u>200</u>	<u>-1</u>

All but (1) can be expressed as a S.O. Order Condition.

# Detail on this back-substitution:

In particular, with  $b_p = L_{p+1,p}$  and  $L_{q,q-1}$ , we first "back-compute" with  $L_{q,q-1}$  from the lower-right corner:

$c_1$							
$c_2$		$L_{2,1}$					
.		...					
$c_{p-1}$		$L_{p-1,1}$	$L_{p-1,2}$	..	$L_{p-1,s-2}$		
$c_p$		$L_{p,1}$	$L_{p,2}$	..	$L_{p,p-2}$	$L_{p,p-1}$	
		$L_{p+1,1}$		..	$L_{p+1,p-2}$	$L_{p+1,p-1}$	$L_{p+1,p}$

to get  $a_{q,q-1} = (L_{q,q-1})/L_{q+1,q}$ ,  $q = p, \dots, 1$ ,

$c_1$							
$c_2$		$a_{2,1}$					
.		..					
$c_{p-1}$		.	.	..		$a_{p-1,p-2}$	
$c_p$		.	.	..			$a_{p,p-1}$
		.	.	..			$b_p$

# Next diagonal of back-substitution:

Next, with  $L_{q,q-2}$ , we back-compute up the next diagonal:

$c_1$						
$c_2$		$L_{2,1}$				
.		...				
$c_{p-1}$		$L_{p-1,1}$	..	$L_{p-1,p-3}$	$L_{p-1,p-2}$	
$c_p$		$L_{p,1}$	$L_{p,2}$	..	$L_{p,p-2}$	$L_{p,p-1}$
		$L_{p+1,1}$	..	$L_{p+1,p-2}$	$L_{p+1,p-1}$	$L_{p+1,p}$

to get

$$a_{q,q-2} = (L_{q,q-1} - L_{q+1,q-1} * a_{q-1,q-2}) / L_{q+1,q}, \quad q = p-1, \dots, 1,$$

$c_1$						
$c_2$		$a_{2,1}$				
.			↖	↖		
$c_{p-1}$		.	..	$a_{p-1,p-3}$	$a_{p-1,p-2}$	
$c_p$		.	.	..	$a_{p,p-2}$	$a_{p,p-1}$
		.	.	..	.	$b_{p-1} \quad b_p$

# Next diagonal of back-substitution:

Next, with  $L_{q,q-2}$ , we back-compute up the next diagonal:

$$\begin{array}{c|cccccc}
 c_1 & & & & & & \\
 c_2 & L_{2,1} & & & & & \\
 \cdot & \dots & & & & & \\
 c_{p-1} & L_{p-1,1} & \dots & L_{p-1,p-3} & L_{p-1,p-2} & & \\
 c_p & L_{p,1} & L_{p,2} & \dots & L_{p,p-2} & L_{p,p-1} & \\
 \hline
 \text{to get} & L_{p+1,1} & & \dots & L_{p+1,p-2} & L_{p+1,p-1} & L_{p+1,p}
 \end{array}$$

$\Downarrow$

$$a_{q,q-2} = (L_{q,q-1} - L_{q+1,q-1} * a_{q-1,q-2}) / L_{q+1,q}, \quad q = p-1, \dots, 1,$$

$$\begin{array}{c|cccccc}
 c_1 & & & & & & \\
 c_2 & a_{2,1} & & & & & \\
 \cdot & \swarrow & \swarrow & \swarrow & & & \\
 c_{p-1} & \cdot & \dots & a_{p-1,p-3} & a_{p-1,p-2} & & \\
 c_p & \text{and so on} & \cdot & \dots & a_{p,p-2} & a_{p,p-1} & \\
 \hline
 & \cdot & \cdot & \dots & \cdot & b_{p-1} & b_p
 \end{array}$$

This gives a (p,p)-method for N.H. linear C.C. IVPs.

# $\alpha_j =$ Right Nullspaces

## Definition

Analogously, for each  $j$ , we define  $\alpha_j$  to be a matrix of  $s$  rows whose columns are **right parts** of SOOCs of products up to  $j$  coefficients,

and we use  $\bar{\alpha}_j$  to designate a maximal number of different columns.

$\alpha_j$  will not contain  $\mathbf{e} = [1, \dots, 1]^t$ , but could contain  $(I - 2C)\mathbf{e}$  and for  $j > 1$ ,  $(2C - 3C^2)\mathbf{e}$  and/or  $\mathbf{q}^{[2]}$ .

We'll see an example of  $\alpha_2$  soon. An example of  $\alpha_3$  is

$$\hat{\alpha}_3 = [(2C - 3C^2)\mathbf{e}, \mathbf{q}^{[2]}, (3C^2 - 4C^3)\mathbf{e}, A\mathbf{q}^{[2]}, \mathbf{q}^{[3]}].$$

We observe now that any matrices  $\beta_i$  and  $\alpha_j$  are mutually orthogonal whenever  $1 < i + j \leq p$ . Hence, each contains vectors in the Nullspace of the other.

# The Nullspace Theorem

From these definitions, we have the following:

Theorem 2: For an s-stage method of order p, it is necessary that

$$\beta_i \cdot \alpha_j = 0, \quad 1 < i + j \leq p.$$

To derive methods, we might try to characterize coefficients of a method that possesses such orthogonality properties. To this end, I have studied the **orthogonality properties** of some new methods found using Test21. **Eventually, I found that matrix A of such methods has a very special two-parameter partitioning.**

# Nullspaces for low order Runge–Kutta methods

As an example, consider three-stage methods of general order three:

1.  $\tilde{Q}^{[1]} = \sum_{i=1}^3 b_i - 1 = 0$
2.  $\tilde{Q}^{[1]} - 2\tilde{Q}^{[2]} = \sum_{i=1}^3 b_i(1 - 2c_i) = 0$
3.  $2\tilde{Q}^{[2]} - 3\tilde{Q}^{[3]} = [b_2 \quad b_3] \begin{bmatrix} c_2(2 - 3c_2) \\ c_3(2 - 3c_3) \end{bmatrix} = 0$
4.  $b \cdot \tilde{q}^{[2]} = 0$

Four solutions exist (see Butcher, 2021, p. 63)

# Nullspaces for low order Runge–Kutta methods

As an example, consider three-stage methods of general order three:

1.  $\tilde{Q}^{[1]} = \sum_{i=1}^3 b_i - 1 = 0$
2.  $\tilde{Q}^{[1]} - 2\tilde{Q}^{[2]} = \sum_{i=1}^3 b_i(1 - 2c_i) = 0$
3.  $2\tilde{Q}^{[2]} - 3\tilde{Q}^{[3]} = [b_2 \ b_3] \begin{bmatrix} c_2(2 - 3c_2) \\ c_3(2 - 3c_3) \end{bmatrix} = 0$
4.  $b \cdot \tilde{q}^{[2]} = 0$

Four solutions exist (see Butcher, 2021, p. 63)

We observe that

$$\beta_1 = [b_1 \ b_2 \ b_3] \quad \text{and} \quad \alpha_2 = \begin{bmatrix} 1 & 0 & 0 \\ 1 - 2c_2 & c_2(2 - 3c_2) & q_2^{[2]} \\ 1 - 3c_3 & c_3(2 - 3c_3) & q_3^{[2]} \end{bmatrix};$$

these are orthogonal and  $b \neq 0$ , so that  $\alpha_2$  has rank 2.

Hence,  $\alpha_2$  contains a row or column of zeros, or else has linear dependence, and this leads to the four solutions that exist.

# Outline of New (12,8) Methods

**Almost Theorem 3:** Compute for a 12-stage method:

- 12 nodes with  $c_1, c_6, \dots, c_{12}$  distinct confined by  $c_3 = 2c_4/3$ ,  $c_5 = (4c_4 - 3c_6)/(c_6(6c_4 - 4c_6))$ , and for  $\pi(c) = c(c - c_6)(c - c_7)(c - c_8)$ ,  $c_9$  is chosen so that
$$\left[ \int_0^1 \pi(c) \frac{(c-1)^2}{2!} dc \right] \left[ \int_0^1 \pi(c)(c - c_9) \frac{(c-1)^2}{2!} dc \right]$$
$$= \left[ \int_0^1 \pi(c) \frac{(c-1)^3}{3!} dc \right] \left[ \int_0^1 \pi(c)(c - c_9) \frac{(c-1)}{1!} dc \right].$$
- Choose stages 2 to 9 so that  $q_i^{[k]} = 0$ ,  $k = 1, 2, 3$ .
- Constrain stage 9 so that  $\sum_i b_i c_i^2 a_{i,j} = 0$ ,  $j = 4, 5$ .
- Choose remaining parameters so  $\bar{\beta}_4$  is orthogonal to  $q^{[4]}$ .
- $L_{i,j}$  (with  $L_{i,j} = 0$ ,  $j = 2..5$ ) and back-substitution, for the weights  $b_i$  and stages 12 to 10.

**Then, the method has order 8.**

# Partial proof

## Proof.

Conditions A and B follow from  $q^{[k]}$ ,  $k = 1, 2, 3$ , and  $L_{i,j}$ . Also, values for  $q_i^{[k]}$  force Conditions D to collapse to Conditions C. To establish Conditions C, formulas among A, C, b are used:

- $L_{i,j}$  with  $i = 13, 12$  imply  $bA = b(I - C)$
- post-multiplication of  $bA - b(I - C)$  by A, C, AA, CC, AC, CA
- $bCCA * q^{[4]} = 0$

These imply  $bAC$ ,  $bCA$ ,  $bCAA$ ,  $bACC$  lie in the row space of  $\hat{\beta}_4$ ;  $bAAC$ ,  $bCAC$ ,  $bACA$ , added to linear combinations of  $C^k$ ,  $k = 0..4$  can be shown to be orthogonal to  $q^{[4]}$  by direct computation. These imply most of Conditions C hold.  $\square$

This will leave one arbitrary coefficient in row 8 of A (selected as  $a_{8,7}$ ). As well, under further constraints,  $a_{7,6}$  is arbitrary.

  - Stage 8:  $a_{8,2} = a_{8,3} = 0, a_{8,7}, q_8^{[k]} = 0, k = 1, 2, 3 > \text{SO}=3$
  - Stage 9:  $a_{9,2} = a_{9,3} := 0, q_9^{[k]} = 0, k = 1, 2, 3 > \text{SO}=3$
- $$L_{13,10}(c_{10} - c_{12})(c_{10} - c_{11})\sum_{j=k+1}^9 L_{11,j} a_{j,k}$$
- $$-L_{11,10}\sum_{j=k+1}^9 L_{13,j}(c_j - c_{12})(c_j - c_{11})a_{j,k} = 0, \quad k = 4, 5.$$
- Stages 12..10 and  $b_i$ : Observe  $b_i = L_{13,i}, i = 1..12$ , and use back-substitution on  $L_{14-k,i}, k = 2..4, i = 13 - k, \dots, 1$  to get  $a_{14-k,i}, k = 2..4, i = 13 - k..1$ .

But to get order 8 more is needed to replace  $q^{[4]} = 0$ .

## Proof.

For  $c_6 = 1/2$ , the matrix for V1 has rank 5, so V1 is a right Nullvector of  $\bar{\beta}_4$ . Also, R1 is a left Nullvector of  $\bar{\alpha}_4$ . The matrix for V2 has rank 4, and so V2 is a right Nullvector of  $\bar{\beta}_3$ . As well, R2 is a left Nullvector of  $\bar{\alpha}_3$ . These seem sufficient to prove that coefficients  $\{b, bh, \hat{A}, c\}$  yield a (13,7-8) pair.  $\square$

For each traditional (13,7-8) pair with  $c_6 = 1/2$  and a value of  $a_{8,7}$ , this yields a new family of such pairs in the parameter  $a_{7,6}$ . While we have exchanged the freedom to choose an arbitrary value for  $c_6$  to make  $a_{7,6}$  a parameter, we have derived a new family of pairs.

A code for obtaining pairs of this new type is similar to that for the traditional pairs. When  $c_6 = 1/2$ , I have used this code to optimize over the range of arbitrary nodes,  $a_{7,6}$  and  $a_{8,7}$ .

# But wait! I wanted to mention one more thing...

This week Paul Muir and Ray Spitiri provided me with a link to an Undergraduate Thesis by David K. Zhang. This thesis may be found at

<https://arxiv.org/abs/1911.00318>

The thesis discusses the use of Machine Learning that David K. Zhang utilized to obtain approximate coefficients for some (16-10) methods. John has been searching for such methods for over 40 years. For two methods displayed in the Appendices, coefficients are recorded in 70 decimal digit floating point form.

I have applied a MAPLE version of the code John and I wrote in 1970 to find that coefficients of the first method displayed satisfies the order conditions to 68 digits.

I have also applied a few of the tools I have described above to show for this first method that  $\beta_4$  is orthogonal to each of  $q^{[4]}$ ,  $q^{[5]}$ ,  $q^{[6]}$ , and as well to each of three polynomials of degrees 4,5, and 6 that are analogs of  $P_4(C)$  defined above. It might be hoped that such tools may lead to a precise characterization of such methods having exact coefficients.

I have applied a MAPLE version of the code John and I wrote in 1970 to find that coefficients of the first method displayed satisfies the order conditions to 68 digits.

I have also applied a few of the tools I have described above to show for this first method that  $\beta_4$  is orthogonal to each of  $q^{[4]}$ ,  $q^{[5]}$ ,  $q^{[6]}$ , and as well to each of three polynomials of degrees 4,5, and 6 that are analogs of  $P_4(C)$  defined above. It might be hoped that such tools may lead to a precise characterization of such methods having exact coefficients.

Perhaps some of you may wish to do some studies of this. I also hope that I have given John a new perspective on this problem he has studied for so many years.

**HAPPY BIRTHDAY JOHN**
